

# Adequacy of PCF

Natalie Ravenhill

July 14, 2016

# Aim of the Project

- Study the operational and denotational semantics of the programming language PCF
- Prove that these semantics are equivalent at base type, by proving a theorem called Adequacy

# Proposal up to now...

Week	Date	Task
1	06/06/16	Domains
2	13/06/16	Domains
3	20/06/16	Denotational Semantics
4	27/06/16	Denotational Semantics
5	04/07/16	Operational Semantics
6	11/07/16	Operational Semantics ( <i>Inspection Week</i> )

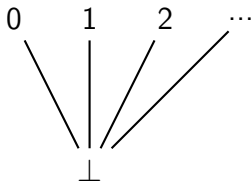

# Domain Theory

A domain is a set  $X$ , an element  $\perp \in X$  and a relation  $\sqsubseteq \subseteq X \times X$  such that:

- $\forall x \in X. \perp \sqsubseteq x$
- $\sqsubseteq$  is a partial order
- For all chains  $\vec{x}, \vec{x}$  has a limit. To prove this there are two properties we must prove
  - $\exists z \in X. \forall i. x_i \sqsubseteq z$  (*upper bound*)
  - $\exists z \in X. \forall y. (\forall i. x_i \sqsubseteq y) \Rightarrow z \sqsubseteq y$  (*least upper bound*)

## Flat Domain of Natural Numbers

$$\mathbb{N}_\perp = \mathbb{N} \cup \{\perp\}$$

$$\sqsubseteq = \{(\perp, \perp)\} \cup \{(\perp, n), (n, n) \mid n \in \mathbb{N}\}$$

Proved this is a domain

## Continuous Functions

For two domains,  $\mathbb{X} = (X, \perp_X, \sqsubseteq_X)$  and  $\mathbb{Y} = (Y, \perp_Y, \leq_Y)$  The set  $Cont(X, Y) = \{f : X \rightarrow Y\}$  where:

- $\forall x, x' \in X. x \sqsubseteq_X x' \Rightarrow f(x) \leq_Y f(x')$
- $x \in Chain(X) \Rightarrow f(\sqcup x_i) = \sqcup f(x_i)$

The bottom element of this set is  $\perp = \lambda x. \perp(x)$ .

The relation  $\sqsubseteq_{Cont(X,Y)}$  is defined as

$$\sqsubseteq_{Cont(X,Y)} = \{(f, g) \mid f, g \in Cont(X, Y) \wedge \forall x \in X. f(x) \leq_Y g(x)\}$$

Proved this is a domain.

# Fixpoint Theorem

Continuous Functions are used to model fixpoint recursion.

## Theorem

*Every continuous function  $f : X \rightarrow X$  has a least fixpoint, which is the limit of the chain  $\perp \sqsubseteq f(\perp) \sqsubseteq f^2(\perp) \sqsubseteq \dots$*

## Proof.

in 2 steps:

- 1 Prove limit of chain is a fixpoint
- 2 Limit  $\sqsubseteq$  any other fixpoint

Syntax of PCF:

$$\begin{aligned}
 A &::= \text{Nat} \mid A \rightarrow B \\
 e &::= \lambda x : A. e \mid e \ e \mid x \\
 &\mid z \mid s(e) \mid \text{case } (e, z \rightarrow e_0, \\
 &\quad s(n) \rightarrow e_s) \\
 &\mid \text{fix } x : A . e
 \end{aligned}$$

# Operational Semantics

Small step operational semantics:

$$\frac{}{(\lambda x : A. e) e' \mapsto [e'/x]e}$$

$$\frac{}{\text{case } (z, z \rightarrow e_0, s(x) \rightarrow e_s) \mapsto e_0}$$

$$\frac{}{\text{case } (s(v), z \rightarrow e_0, s(x) \rightarrow e_s) \mapsto [v/x]e_s}$$

$$\frac{}{\text{fix } x : A. e \mapsto [\text{fix } x : A. e/x]e}$$

# Operational Semantics

Congruence Rules:

$$\frac{e_0 \mapsto e'_0}{e_0 \ e_1 \mapsto e'_0 \ e_1}$$

$$\frac{e \mapsto e'}{s(e) \mapsto s(e')}$$

$$\frac{e \mapsto e'}{\text{case } (e, z \rightarrow e_0, s(x) \rightarrow e_S) \mapsto \text{case } (e', z \rightarrow e_0, s(x) \rightarrow e_S)}$$

# Type Safety

*i.e. "well typed terms can't go wrong"*

Assumed from following two theorems:

## Type Preservation

*If  $\Gamma \vdash e : A$  and  $e \mapsto e'$ , then  $\Gamma \vdash e' : A$*

## Type Progress

*If  $\vdash e : A$  then  $e \mapsto e'$  or  $e$  is a value.*

# Typing Rules

We need a typing rule for each expression in PCF:

$$\begin{array}{c} \text{VARIABLES} \\ \Gamma(x) = A \\ \hline \Gamma \vdash x : A \end{array}$$

$$\begin{array}{c} \text{ZERO} \\ \hline \Gamma \vdash z : \text{Nat} \end{array}$$

$$\begin{array}{c} \text{SUCC} \\ \Gamma \vdash e : \text{Nat} \\ \hline \Gamma \vdash s(e) : \text{Nat} \end{array}$$

$$\begin{array}{c} \text{CASE} \\ \Gamma \vdash e : \text{Nat} \quad \Gamma \vdash e_0 : A \quad \Gamma, x : \text{Nat} \vdash e_s : A \\ \hline \Gamma \vdash \text{case } (e, z \rightarrow e_0, s(x) \rightarrow e_s) : A \end{array}$$

# Typing Rules

We need a typing rule for each expression in PCF:

APPLICATION

$$\frac{\Gamma \vdash e : A \rightarrow B \quad \Gamma \vdash e' : A}{\Gamma \vdash e \ e' : B}$$

ABSTRACTION

$$\frac{\Gamma, x : A \vdash e : B}{\Gamma \vdash \lambda x : A. e : A \rightarrow B}$$

FIX

$$\frac{\Gamma, x : A \vdash e : C}{\Gamma \vdash \text{fix } x : A. e : C}$$

# Type Lemmas

Lemmas we proved for use in Type Safety:

## Type Weakening

*If  $\Gamma \vdash e : A$  then  $\Gamma, x : C \vdash e : A$*

If we add a new variable to the context, this does not change the type of our given expression.

## Proof.

By induction on value of  $e$

# Substitution Rules

## Variables

$$[e/x]x = e$$

$$[e/x]y = y$$

## Zero

$$[e/x]z = z$$

## Successor

$$[e/x]s(e') = s([e/x]e')$$

## Case

$$[e/x] (\text{case } (e', z \rightarrow e_0, s(x) \rightarrow e_s)) = \\ \text{case } ([e/x]e', z \rightarrow [e/x]e_0, s(x) \rightarrow [e/x]e_s)$$

# Substitution Rules

## Application

$$[e/x]e_0 \ e_1 = [e/x]e_0 \ ([e/x]e_1)$$

## $\lambda$ Abstraction

$$[e/x](\lambda x : A. e') = \lambda x : A. e'$$

$$[e/x](\lambda y : A. e') = \lambda y : A. [e/x]e'$$

# Type Lemmas

## Type Substitution

*If  $\Gamma \vdash e : A$  and  $\Gamma, x : A \vdash e' : C$  then  $\Gamma \vdash [e/x]e' : C$*

If we have an expression of type  $C$  in a context extended with  $x : A$ , then we can replace  $x$  with this in an expression  $e'$  of type  $C$ .

## Proof.

By induction on  $e'$  □

Proof uses Weakening, for example in the case for case

# Preservation

## Type Preservation

*If  $\Gamma \vdash e : A$  and  $e \mapsto e'$ , then  $\Gamma \vdash e' : A$*

This says that if  $\Gamma \vdash e : A$  and there is an evaluation rule mapping the expression  $e$  to another one in one step, then the new expression has the same type.

## Proof.

By induction on on evaluation rules  $e \mapsto e'$  for each possible value of  $e$  □

Proof uses Substitution for example, in the case of  $(\lambda x : A. e)e'$

## Type Progress

*If  $\vdash e : A$  then  $e \mapsto e'$  or  $e$  is a value.*

This says that for any closed term (one with an empty typing context), it either evaluates to another expression or is a value. A value is zero, successor of a number, or a function  $\lambda x : A. e$ .

## Proof.

By induction on  $e$  □

# Denotational Semantics

Denotational Semantics use the **Scott Model**, defined as a function from a typing context to a domain:

$$\llbracket - \rrbracket : \textit{Type} \rightarrow \textit{Domain}$$

Defined inductively as:

$$\llbracket \textit{Nat} \rrbracket = \mathbb{N}_{\perp}$$

$$\llbracket A \rightarrow B \rrbracket = \llbracket A \rrbracket \rightarrow \llbracket B \rrbracket$$

# Denotation of Typing Contexts

On typing contexts the function is:

$$\llbracket - \rrbracket_{Ctx} : Context \rightarrow Domain$$

Defined inductively as:

$$\llbracket \cdot \rrbracket_{Ctx} = \mathbb{1}$$

$$\llbracket \Gamma, x : A \rrbracket_{Ctx} = \llbracket \Gamma \rrbracket \times \llbracket A \rrbracket$$

Where  $\mathbb{1}$  is the single element domain and non empty contexts are products of domains.

# Denotational Semantics of Terms

Given a well typed term  $\Gamma \vdash e : A$  we have

$$\llbracket \Gamma \vdash e : A \rrbracket \in \llbracket \Gamma \rrbracket_{Ctx} \rightarrow \llbracket A \rrbracket$$

We can now inductively define this for every  $e$ :

# Denotational Semantics of Terms

## Variables

$$\llbracket \Gamma \vdash x_i : A_i \rrbracket = \lambda \gamma \in \llbracket \Gamma \rrbracket. \pi_i(\gamma)$$

## Zero

$$\llbracket \Gamma \vdash z : \mathit{Nat} \rrbracket \gamma = 0$$

## Successor

$$\llbracket \Gamma \vdash s(e) : \mathit{Nat} \rrbracket \gamma = \text{Let } v = \llbracket \Gamma \vdash e : \mathit{Nat} \rrbracket \gamma \text{ in}$$

$$\begin{cases} v + 1 & \text{if } v \neq \perp \\ \perp & \text{if } v = \perp \end{cases}$$

# Denotational Semantics of Terms

## Case

$\llbracket \Gamma \vdash \text{case } (e, z \mapsto e_0, s(y) \mapsto e_s) : C \rrbracket \gamma = \text{Let } v = \llbracket \Gamma \vdash e : \text{Nat} \rrbracket \gamma \text{ in}$

$$\begin{cases} \llbracket \Gamma \vdash e_0 : C \rrbracket \gamma & \text{if } v = 0 \\ \llbracket \Gamma \vdash e_s : C \rrbracket \gamma & \text{if } v = n + 1 \\ \perp & \text{if } v = \perp \end{cases}$$

# Denotational Semantics of Terms

## Application

$$\begin{aligned} \llbracket \Gamma \vdash e \ e' : B \rrbracket \gamma &= \text{Let } f = \llbracket \Gamma \vdash e : A \rightarrow B \rrbracket \gamma \text{ in} \\ &\quad \text{Let } v = \llbracket \Gamma \vdash e' : A \rrbracket \gamma \\ &\quad \text{in } f(v) \end{aligned}$$

## $\lambda$ abstraction

$$\llbracket \Gamma \vdash \lambda x : A. e : A \rightarrow B \rrbracket \gamma = \lambda a \in \llbracket A \rrbracket. \llbracket \Gamma, x : A \vdash e : B \rrbracket (\gamma, a/x)$$

## Fixpoint

$$\llbracket \Gamma \vdash \text{fix } x : A. e : A \rrbracket \gamma = \text{fix}_{\llbracket A \rrbracket} (\lambda a \in \llbracket A \rrbracket. \llbracket \Gamma, x : A \vdash e : A \rrbracket (\gamma, a/x))$$

# Correctness

Now we can relate the Operational Semantics to the Denotational semantics with the following theorem:

## Theorem

*If  $\Gamma \vdash e : A$  and  $e \mapsto e'$  and  $\gamma \in \llbracket \Gamma \rrbracket$ , then*  
$$\llbracket \Gamma \vdash e : A \rrbracket \gamma = \llbracket \Gamma' \vdash e' : A \rrbracket \gamma$$

which says that for a well typed expression  $e$ , if it maps to another expression  $e'$ , then its denotation will be equal to that of the new expression in its new context.

## Proof.

by induction on  $e \mapsto e'$ , so the cases are on the evaluation rules. We can use the fact that  $f(\text{fix}(f)) = \text{fix}(f)$  and a substitution lemma

# Substitution Lemma

## Lemma

If  $\Gamma \vdash e : A$  and  $\Gamma, x : A \vdash e' : C$  and  $\gamma \in \llbracket \Gamma \rrbracket$ , then  
$$\llbracket \Gamma \vdash [e/x]e' : C \rrbracket \gamma = \llbracket \Gamma, x : A \vdash e' : C \rrbracket (\gamma, \llbracket \Gamma \vdash e : A \rrbracket \gamma / x)$$

## Proof.

By induction on  $e'$

# Adequacy

Adequacy is the following theorem:

## Theorem

*If  $\vdash e : \text{Nat}$  (ie.  $e$  is a closed term of type  $\text{Nat}$ ) and  $\llbracket e \rrbracket = n$  then  $\llbracket e \rrbracket = n \Leftrightarrow e \mapsto^* n$*

Correctness is one part of this. If we wanted to prove the opposite direction, we cannot do this just using induction.

So we need Logical Relations for the other direction.
